The batch glass reactor are vessels that are used for several processes that include product mixing, chemical reactions, crystallization, and batch distillation. The batch reactors include combinations of multiple tanks, a cooling-system and storage tanks with agitators. These vessels are available in different sizes and will depend on the industries that they are used in.

2 Conversion and Reactor Sizing 2.1 Batch Reactor Design Equations Conversion (of substance A) is defined as $X = \frac{\text{moles of A reacted}}{\text{moles of A fed}}$ - This can be rephrased mathematically as $X = \frac{N_{i0} - N_i}{N_{i0}} = \frac{C_{i0} - C_i}{C_{i0}}$

The number of moles of A in the reactor after a conversion X has been achieved is $N_A = N_{A0} (1 - X)$ By differentiating the above expression with respect to t and plugging it into the expression for the

Batch reactor with single external cooling jacket The single jacket design consists of an outer jacket which surrounds the vessel. Heat transfer fluid flows around the jacket and is injected at high velocity via nozzles. The temperature in the jacket is regulated to control heating or cooling.

Batch reactor - Wikipedia

By sizing a chemical reactor we mean we're either deterring the reactor volume to achieve a given conversion or determine the conversion that can be achieved in a given reactor type and size. Here we will assume that we will be given $-r_A = f(X)$ and F_{A0} . In chapter 3 we show how to find $-r_A = f(X)$.. Given $-r_A$ as a function of conversion, $-r_A = f(X)$, one can size any type of reactor.
